ABSTRACT

A software package for processing conductivity-temperature-depth (CTD) data is described. The package includes features for editing, correcting, filtering and pressure sorting to produce working data files for graphic and analysis work.

ACKNOWLEDGMENTS

This work is a description of software developed while the author was employed by the Naval Oceanographic Office (Code 7210). The vast majority of the programming, testing, debugging and use of the described software was performed by Mr. William Teague. Many of the algorithms used were adapted from programs written by Mr. Frank Mulher, who also wrote the preparatory programs. The careful work of Mr. Carlos Mayoral and his colleagues in Code 6320 in determining sensor time-responses and the expert help of Dr. Tom Davis of Code 022 in designing deconvolution filters for temperature, allowed the inclusion of data quality improvement features.

This work was supported by the Ocean Measurements Program through the Ocean Programs Management Office at NORDA, funded by Program Element 63704N, Dr. Rudy Hollman, program manager.

A COMPUTER PROGRAM FOR PROCESSING CONDUCTIVITY-TEMPERATURE-DEPTH (CTD) DATA

I. INTRODUCTION

CTD (conductivity-temperature-depth) data acquired with a Neil Brown Instrument Systems CTD system (or equivalent data) require certain processing steps before they are generally usable for oceanographic analysis. This note describes a processing software package (CTDPRG), which was developed at the Naval Oceanographic Office and has been used in a production mode since 1978. Some minor modifications have been made since that time, but the basic structure has not changed.

Input data for CTDPRG must be in the form of a Fast Easy Binary (FEB) file (Hallock, 1980) and must consist of the physical variables: pressure (dbar), temperature ($^{\circ}\text{C}$) and conductivity (mmho/cm). Hence, a pre-processing step is required which will be specific to the original data recording format. Output is quite flexible ranging from the input data itself through corrected, pressure-sorted and subsampled data with calculated quantities such as salinity and density.

Section II is a general, functional description of algorithms used. Section III provides details for running the programs with several examples of run setups. Section IV contains complete program listings.

II. GENERAL DESCRIPTION

CTDPRG is designed to handle CTD data acquired as vertical profiles, horizontal tows, or a combination of these. The program was developed around vertically profiled data; however, and much of its complexity goes toward converting the time-base CTD data to functions of pressure, when this conversion is required.

The following list is a summary of the processing steps performed by CTDPRG.

- Read input controls from cards or keyboard.
- Read data from mass storage file.
- Correct isolated spikes (wild data points).
- Apply time-domain filters to pressure, temperature and conductivity (this includes T-C matching).
- Correct conductivity values based on water sample comparisons.
- Apply temperature-pressure dependent cell correction.
- Separate up-going and down-going profiles.
- Pressure-sort data by averaging into 0.1 dbar intervals.

- Low-pass filter, in pressure, and subsample to multiple of 0.1 dbar.
- Compute selected quantities (e.g., salinity, sigma-t) from P, T, C.
- Write results to mass-storage files.

All steps (except the first three and last) are optional and can be selected in several combinations.

Input Data Sets

The basic unit of processing is the input data set. This is, typically, a single CTD cast (down and up, if both were recorded). It might be, however, a series of down and up profiles acquired during one instrument deployment. Usually an input data set corresponds to a single input file, but this is not required. There may be more than one data set per file or a data set may span several files. All this is handled by the input controls. The input data set is in a FEB-file containing time, pressure (dbar), temperature (°C) and conductivity (mmho/cm).^{*} Additional variables could be carried with minor modifications. The last FEB-segment in the data set must have IDOCR(1)=1; preceding segments (for multi-segment data sets) must have IDOCR(1)=0. Input files are thus prepared by a pre-processing program that is tailored for the particular instrument and deployment mode.

Time-Domain Filters

One of the most significant problems with CTD data has been the effects of the response mismatch between temperature and conductivity sensors. A number of attempts have been made to correct this through the design and application of filters. The most widely used method is that described by Fofonoff et al. (1974), which assumes an exponential response for the temperature sensor. More recently, as a result of work done at the Naval Oceanographic Office (NOO) involving direct measurement of instrument response, specific filters have been designed for temperature and conductivity, based on experimentally determined sensor response functions (see Mayoral, 1982). In CTDPGR there are three options: no T-C filtering, filtering, the three-point Fofonoff method (the user specifies only the time-constant), or explicitly supplied filters of the user's choice. These are applied to the raw data, in the time domain, prior to other processing.

A smoothing filter is automatically applied to pressure data to remove high-frequency sensor noise.

Conductivity Calibration

With the newer conductivity cells on the MK III CTD systems, coupled with proper cleaning procedures and frequent laboratory calibration adjustments, conductivity data seldom

^{*}See Hallock (1980) for details on FEB-file structure.

has to be adjusted from the recorded values. However, if salinity checks derived from water samples indicate an offset from proper calibration, a multiplicative correction can be supplied by the user. There is also a manufacturer-supplied correction for pressure and temperature distortion which is applied following the filtering step.

Upcasts and Downcasts

If no editing based on pressure is to be done (i.e., no identification of upcasts, downcasts or constant level data), following conductivity correction, selected additional variables are computed, and an output data set is written that contains the same number of scans (cycles) as the input.

A second option is to retain only upcasts and/or downcasts, based on user defined pressure limits, which are then written as separate output data sets, following computation of additional variables.

A third option, which necessitates the second, is to convert each upcast/downcast to a pressure series as opposed to a time series. This case assumes that the instrument descent/ascent rate is 2 m/sec or less. (If this value is exceeded in the mean, some software modifications would be necessary.) At a nominal descent/ascent rate of 1 m/sec, about three scans of data are acquired every 0.1 dbar. If pressure sorting is selected, time, temperature and conductivity values in 0.1 dbar intervals are averaged, creating a pressure series at that resolution. Retrograde (in pressure) data are rejected. The pressure series is then subsampled at some user-defined, integral multiple of 0.1 dbar following the application of a low-pass filter to prevent aliasing. The filter is automatically generated, and its cutoff wavenumber is the new Nyquist wavenumber of the subsampled series. At this point additional variables are computed and data are written to output files. The third option allows the user to select a degree of smoothing/subsampling commensurate with his requirements.

Computed Variables

Including the four input variables, up to twelve are available as output. The user may select any subset of these. The eight computed variables are as follows:

- Salinity (parts per thousand [ppt]) or S: computed with pressure, temperature and conductivity ratio, according to Bennett (1976), Dauphine and Klein (1977) or Lewis (1980).
- Sigma or σ : the in situ density of a water parcel. Computed with pressure, temperature, and salinity according to Fofonoff (1962). ($\text{Sigma} = (\text{density (g/cc)} - 1.) * 1000.$)
- Sigma-t or σ_t : the density of a water parcel with in situ temperature and salinity but at atmospheric pressure.
- Brunt-Väisälä Frequency (cycles per hour) or N: computed with pressure, temperature, and salinity according to Fofonoff

(1962). Essentially a local potential density derivative. The convention is adopted: $N = \sqrt{|N^2|} \text{sgn}(N^2)$ to allow for instabilities.

- Sound Speed (m/sec): computed with pressure, temperature, and salinity according to Wilson (1960).

- True Depth: for most purposes, pressure in decibars can be interpreted as depth in meters; however, this assumes an average water density of 1.02 g/cc. If depth accurate to more than a few percent are required, this variable can be selected. It is an approximation to:

$$z = \int_0^p \frac{\alpha}{g} dp$$

where α = specific volume,
 g = acceleration of gravity,
 p = pressure,
 z = depth below surface,

- Potential Temperature ($^{\circ}\text{C}$) or θ : The temperature that a parcel of water would have if brought adiabatically to the surface. Computed with pressure, temperature and salinity according to Fofonoff (1962).

- Potential Density or σ_0 : σ_t using θ rather than in situ temperature; the density of a water parcel brought adiabatically to the surface. (σ_0 is calculated using the σ_t routine with θ from the above routine.)

A typical standard processing product might be: retain only downcasts at 1 meter resolution, and store pressure, temperature, salinity and σ_t . This provides a compact version of data for hydrographic analysis work. The best "standard" file is likely to be different for each user group; thus, it is recommended that the input files (edited, raw data) be considered the primary, archived data base.

III. DETAILS OF OPERATION

This section consists of two parts: a tour of CTDPRG and its subroutines; a tutorial on setting up input and running the program.

Functional Program Description

Figure 1 is a block diagram of all the routines in the package. CTDPRG is the driver, whose functions are to read all input controls, to set up filters to be used on input data, and to initiate the processing of each input data set by calling ACCESS.

GENWHF generates a three-point deconvolution filter for temperature based on a user-specified, sensor time-constant. This is described in detail by Fofonoff et al. (1974).

GENFLT is a general filter generating routine (see Brooks, 1976). It is called in CTDPRG to produce a low-pass filter for pressure data to remove sampling noise.

ACCESS controls the majority of the processing. Input data cycles (scans) are accessed, one at a time, via calls to GETREC. If pressure sorting is not selected, output segments are prepared using a user-specified combination of variables from the input as well as quantities computed via DERIVE.

When upcast/downcast separation is specified, each upcast/downcast becomes a separate data set and is written to unit 3/2. Otherwise, all output goes to unit 2 as one data set.

With pressure sorting, which necessitates upcast/downcast separation, input data cycles in 0.1 dB intervals are averaged, producing a pressure series at that resolution. Retrograde data, which result from ship motion or winch reversals, are rejected. For a nominal descent rate of 1 meter per second there should be about 3 cycles per interval. If an interval should turn up empty, it is filled with data from the previous interval. If descent rates systematically exceed 1.5-2 m/s this interval should be increased accordingly.

The pressure sorted data can be subsampled at integral multiples, say n , of 0.1 dB. When this is done, ACCESS calls GENFLT to produce a low-pass filter which is applied to the 0.1 dB data, centered at every n th cycle. The cutoff of the filter is at the new Nyquist of the subsampled series and prevents aliasing. For example: $n = 10$ implies subsampling every 1 dB; cutoff (half-amplitude point) is at 0.5 cycles/dB; the filter is applied only where samples are to be extracted (e.g., every 10th point), thus avoiding unnecessary computation.

Following pressure sorting and subsampling, DERIVE is called for selected computed variables. Segments are then assembled and written to the output file(s).

Subroutine GETREC is the input program. It reads segments from the input file (unit 4), applies conductivity cell corrections, pressure smoothing filters, conductivity-temperature matching filters and pressure limits. Data are then passed to ACCESS, one cycle at a time. Upper and lower pressure limits, specified by the user, are employed by GETREC to distinguish upcast and downcast data.

NBCCC applies a manufacturer supplied cell correction to conductivity which compensates for pressure and temperature distortions of cell geometry. It also applies a user-specified multiplicative conductivity adjustment (usually = 1.) which corrects for salinity offsets determined by field comparisons.

Time-domain filters are described in Section II.

When an end-of-data set (IDOCR(1) = 1) is detected, control returns to the main program and new input cards are sought. If an end-of-file is encountered, however, GETREC calls IUSER which attempts to dynamically attach another user-specified file name to unit 4. If no file name is supplied, the program terminates. (On some machines dynamic control commands may not be permitted, thus requiring one execution per input file.)

Subroutine DERIVE accepts a cycle of pressure, temperature, conductivity and time from access and, after calling the appropriate variable computation routines, restructures the cycle according to user specifications. The variable computation routines are described in Section II.

Subroutine ZREAD and ZWRIT (described by Hallock, 1980) are input and output routines for FEB-files. A call to ZREAD/ZWRIT transfers one segment of data between main memory and a mass storage file. Typically, a data set (e.g., CTD profile) consists of several FEB segments; each segment is made up of several header blocks followed by a data block. Segments are written sequentially to a mass-storage (disk) file by nonformatted, FORTRAN I/O statements.

Input Control Cards

Essential information for setting up and running CTDPGR is provided through internal documentation (comment cards), which are presented below.

Input Card 1: Printout identification--up to 48 alphanumeric characters. This can be anything.

Input Card 2: N, LN, NWMAX, KCHOP, NINFIL (Free Format).

N: Subsampling interval for pressure sorted data. Integer multiples of 0.1 dB, e.g., N=20 results in data every 2 dB. N=0 results in no pressure sorting.

LN: Sharpness factor for subsampling filter. This is an integer equal to 1 or greater. Larger values require more computer time. ($m = LN \cdot N$ = half-width of filter. See, GENER1 in Brooks, 1976, for a more detailed explanation.)

NWMAX: Maximum no. of cycles in output segments. Typically, 1000.

KCHOP=1: Process all data. No pressure sorting or subsampling. Pressure limits are not applied. Output goes to unit 2.

KCHOP=2: Pressure sort and subsample by N (unless N = 0). Output downcasts to unit 2, upcasts to unit 3.

KCHOP=3: Same as 2 but output only downcasts.

KCHOP=4: Same as 2 but output only upcasts.

NINFIL: No. of input file names to be supplied.
If =0, one input file is assumed on unit 4. Otherwise, supplied names are dynamically attached to unit 4 by IUSET (presently configured for UNIVAC).

Input Card 3: (IND(I), I=1, 12) (Free format) output variable selection. A string of 12 integers (1 for yes, 0 for no) indicating variables to be output from the following list: Time, pressure, temperature, salinity, sigma-t, sigma, Brunt-Väisälä frequency, sound speed, depth, potential temperature, potential density.

Input Filename Cards: up to 24 alphanumeric characters, left-justified. If NINFIL=0, no cards are expected.

The following group of cards, the data set card and pressure limit cards, is repeated for each input data set to be processed. .

Input Data Set Card: NMSER, NPLIMS, CFTR, TIMCON, ISAL
(Free Format)

NMSER: Sequence no. of input data set to be processed. (Usually this is equal to 1, but if there were, say, n data sets to be skipped beginning in the first input file, NMSER would be set to n+1.)

NPLIMS: No. of pressure limit cards for this data set.

CFTR: Conductivity cell correction factor (default=1).

TIMCON>0: Temperature sensor time constant divided by sampling time interval. WHOI (Fofonoff et al. temperature deconvolution.)

=0: No. temperature or conductivity filtering.

=-1: Use same filters that were used for previous data set. (Not permissible for first data set.)

=-5: Read special filters from cards (unit 5) following pressure limit cards.

All Else: Read special filters from file on unit 8.

ISAL = 0: Salinity computed according to Lewis and Perkin (1980)

= 1: Salinity computed according to Bennet-Dauphinee.

Pressure/Cycle Limit Cards: PTOP, PBOT, DELTAP, I1, I2
(Free format)

PTOP, PBOT are upper lower pressure limits to be applied to input data cycles between cycles I1 and I2. Each sequence of cycles spanning this pressure interval is made into an output data set. Pressure limits are irrelevant for KCHOP=1.

DELTAP is a slop factor (usually about 2 dB) that is employed to prevent small pressure fluctuations from tripping up the pressure limit logic. It ensures, for example, that a downcast has ended before the subsequent upcast is recognized. For single-cast data, DELTAP can be set to zero.

I1, I2--There is a global cycle index, IE, which is 1 at the beginning of an input data set. It is incremented for each cycle encountered within the data set. (An input data set typically spans more than one FEB segment and occasionally more than one file.) The first profile start, defined by PTOP, is not sought until IE reaches I1. After each profile is completed, if IE has reached I2, the next pressure limit card is invoked. When the cards are exhausted or the input data set ends, the next data set card is read. This feature allows leading and trailing data within a data set to be skipped, which can save computer time or reject defective data.

Usually, only one pressure limit card is required for each input data set, particularly for a single profile. However, for a series of repeated profiles which are included in a single data set (i.e., a "yo-yo" cast), it may be necessary to change pressure limits several times to maximize data recovery and to reject sections of bad data.

In the simplest case, for a single cast data set, I1 can be set to 1 and I2 to a large number which exceeds the number of cycles in the data set, and everything will be processed. (Default values of 1 and 1,000,000 result for I1 = I2 = 0.)

Special Filter Input: NWTT, NWTC, LAGT, (WT(I), I=1, NWTT), WC(I), I=NWTC) (Free Format)

These are read from cards if TIMCON = -5. If TIMECON = -2, -3, -4, -6, -7,... they are read from a file on unit 8. If TIMCON > -2, this input is not expected. (See TIMCON above.)

NWTT, NWTC: No. of temperature, conductivity, filter weights.

LAGT: No. of cycles to lag temperature relative to pressure and conductivity. (The lag might be built into filter, in which case LAGT = 0.)

WT, WC: Temperature, conductivity filter weights.

Examples of Input Controls

Example 1: Three input files, each containing a downcast and an upcast between about 8 m and 2000 m depth. Only downcasts are to be processed. WHOI (Fofonof, et al., 1974) temperature deconvolution is to be used--time constant is 100 ms, sampling interval is 32 ms. Output pressure resolution is to be 1 dbar. Output variables are to be: P, T, S, σ_t , N. Salinity to be computed by practical salinity scale '78.

Card 1: THIS IS EXAMPLE 1.
Card 2: 10,1,1000,3,3
Card 3: 0,1,1,0,1,1,0,1,0,0,0,0
Card 4: FILE1
Card 5: FILE2
Card 6: FILE3
Card 7: 1,1,1,3.125,0
Card 8: 10,2000,1,1,0

Cards 7 and 8 are repeated for Files 2 and 3.

Example 2: One input file containing a continuous record of two downcasts and two upcasts (i.e., one instrument deployment). The instrument was in the water for one hour before the first downcast began and again following the final upcast. Thus, the first usable data scan is about no. 112,000. The four profiles took about one hour so the last usable scan was around 250,000. Temperature deconvolution filters are to be read from unit 8; a 1.01 conductivity is to be made; salinity is to be computed by Bennett-Dauphinee algorithms. Data are to be subsampled at 50 cm. Both upcasts and downcasts are to be saved, between 100 and 400 dbar.

Card 1: THIS IS EXAMPLE 2.
Card 2: 5,1,1000,2,0 (input assumed on unit 4)
Card 3: 0,1,1,0,1,1,0,1,0,0,0,0
Card 4: 1,1,1.01,-3,1
Card 5: 100,400,2,112000,250000

Example 3: One input file containing 500 downcasts and upcasts between about 90 and 210 dbar ("yo-yo" cast). Data are to be processed as in example 1, saving downcasts at 1 dbar resolution. Prior examination of the data reveals that downcasts 201-208 (scans 1.2×10^6 - 1.248×10^6)

extend only to 190 dbar: three sets of pressure limits are thus required, to recover the maximum amount of data.

Card 1: THIS IS EXAMPLE 3.

Card 2: 10,1,1000,3,0

Card 3: 0,1,1,0,1,1,0,1,0,0,0,0

Card 4: 1,3,1,3.125,0

Card 5: 95,205,2,1,1200000

Card 6: 95,185,2,1200000,1248000

Card 7: 95,205,2,1248000,4000000

Example 4: Input file consists of three downcast-upcast pairs. For diagnostic purposes, it is necessary to process downcast data at original resolution (i.e., no pressure sorting). Output variables are to be: time, pressure, temperature, conductivity and salinity. Pressure limits are 10 to 500 dbar. Special filters for temperature and conductivity are to be supplied on cards.

Card 1: THIS IS EXAMPLE 4.

Card 2: 0,0,1000,3,0

Card 3: 1,1,1,1,1,0,0,0,0,0,0,0

Card 4: 1,1,1,-5,0

Card 5: 10,500,0,1,0

Card 6: 5,5,0,.1,.2,.4,.2,.1,.0625,.125,.625

Card 7: .125,.0625

These are representative examples of how CTDFRG may be used. Many other combinations are possible. Some experimentation may be necessary for unusual requirements.

173 C ***** PRESSURE/CYCLE LIMIT CARDS *****
174 C
175 C PTOP,PROT,DELTAP,I1,I2
176 C
177 C PTOP/PROT ARE UPPER/LOWER PRESSURE LIMITS TO BE
178 C APPLIED TO INPUT DATA CYCLES BETWEEN
179 C CYCLES I1 AND I2. EACH SEQUENCE OF
180 C CYCLES SPANNING THIS PRESSURE
181 C INTERVAL IS MADE INTO AN OUTPUT DATA
182 C SET OR PROFILE. (PRESSURE LIMITS
183 C ARE IRRELEVANT FOR NCHOP=1.)
184 C
185 C DELTAP IS A SLOP FACTOR (USUALLY ABOUT 2 DB)
186 C WHICH IS EMPLOYED TO PREVENT SMALL PRESSURE FLUC-
187 C TUATIONS FROM TRIPPING UP THE PRESSURE LIMIT
188 C LOGIC. IT ENSURES THAT A DOWNCAST HAS ENDED
189 C BEFORE THE SUBSEQUENT UPCAST IS RECOGNIZED, ETC.
190 C
191 C I1,I2 THERE IS A GLOBAL CYCLE INDEX, SAY IE, WHICH
192 C IS SET TO 1 AT THE BEGINNING OF AN INPUT DATA
193 C SET. IT IS INCREMENTED FOR EACH CYCLE ENCOUNTERED
194 C WITHIN THE DATA SET. (AN INPUT DATA SET TYPICALLY
195 C SPANS MORE THAN ONE SEGMENT AND OCCASIONALLY
196 C MORE THAN ONE FILE.) THE FIRST PROFILE
197 C START, DEFINED BY PTOP, IS NOT SOUGHT
198 C UNTIL IE IS GE I1. AFTER EACH PROFILE
199 C IS COMPLETED, IF IE IS GE I2, THE NEXT PRESSURE
200 C LIMIT CARD IS INVOKED. WHEN THE CARDS ARE EX-
201 C HAUSTED OR INPUT DATA SET ENDS, THE NEXT
202 C DATA SET CARD IS READ. IF THE ENTIRE INPUT
203 C DATA SET IS TO BE SCANNED, SET I1=I2=0.
